The Cedar Sleep Study

Primary report | Fictional research fixture

Study overview

The Cedar trial enrolled 120 adults aged 18 to 30. Participants were randomly assigned to a sleep-extension group or a control group. The trial lasted six weeks.

Primary finding

In the Cedar trial, the sleep-extension group improved its attention score by 12 points after six weeks. The control group improved by 2 points. The primary report describes a positive effect on attention.

Sleep duration

Average nightly sleep increased from 6.2 hours to 7.5 hours in the sleep-extension group. Sleep was measured using wrist-worn activity monitors.

Limitations

The Cedar trial was conducted at a single university. Participants knew their group assignment. The small sample and short follow-up limit generalization to older adults.

What was not measured

The Cedar trial did not measure school grades, long-term memory, or mortality. It did not recruit children. No claim about exam performance can be drawn from this trial.
