The Willow Reading Project

Observation summary | Fictional research fixture

Study overview

The Willow project observed 85 adults aged 50 to 65 over four weeks. Researchers recorded reading duration and self-reported concentration. The project was observational, not randomized.

Finding

Adults who read for at least 30 minutes per day reported better concentration. The association does not establish that reading caused the improvement.

Different population

The Willow project did not study sleep extension. Its participants and outcomes differ from those in the Cedar trial. The two projects should not be treated as directly contradictory.

Purpose of this document

This document is fictional and is included as a retrieval distractor and a test of causal overstatement.
